Aims

- To describe basic GPIO in detail.
 - To do this we'll need to learn some digital electronics.
- To describe GPIO's 'alternate function'
- To investigate practicalities of connecting switches and LEDs to GPIO ports.
- To discuss serial data transmission, highlighting some popular protocols

What is GPIO

- GPIO -> General Purpose Input Output
 - Essentially a versatile interface that can be configured by software.
- Does my PC / Laptop provide a GPIO interface?
 - No – PC interface standards are generally focused to the needs of humans.
 - Although USB ports can be adapted to provide GPIO
- The GPIO interface allows the computer to generate electrical outputs (O) and read electrical inputs (I).
- The type of electrical signals that can be handled by the Raspberry Pi GPIO is limited to a class of signals known as digital.
- Digital electrical signals are limited to just two voltages.
 - Logic 1 is usually represented by a high voltage (usually 3.3v or 5v - depends on the fabrication technology)
 - Logic 0 is usually represented by a low voltage (usually 0v)

Two Types of Electrical Signal

- An analogue signal is a continuous wave form that changes smoothly over time.
- A digital signal is discrete. It can have only a limited number of defined values. Often as simple as 0 and 1.

Digital Signals

- An example of digital data is the data stored in the memory of a computer. It is often represented as a series of 1s and 0s
- It is converted to an electrical signal when it is transferred from one place to another, either inside or outside the computer.

Digital Signals

- Computers manipulate digital data.
- A single data bit represents two (binary) states.
- But several data bits can be grouped together to represent numbers as binary code.
- For example, a group of 3-bits comprises 8 unique codes which can be interpreted as representing decimal numbers 0-7.

$$0\ 0\ 0 = (0 \times 2^2) + (0 \times 2^1) + (0 \times 2^0) = 0$$

$$0\ 0\ 1 = (0 \times 2^2) + (0 \times 2^1) + (1 \times 2^0) = 1$$

$$0\ 1\ 0 = (0 \times 2^2) + (1 \times 2^1) + (0 \times 2^0) = 2$$

$$0\ 1\ 1 = (0 \times 2^2) + (1 \times 2^1) + (1 \times 2^0) = 3$$

$$1\ 0\ 0 = (1 \times 2^2) + (0 \times 2^1) + (0 \times 2^0) = 4$$

$$1\ 0\ 1 = (1 \times 2^2) + (0 \times 2^1) + (1 \times 2^0) = 5$$

$$1\ 1\ 0 = (1 \times 2^2) + (1 \times 2^1) + (0 \times 2^0) = 6$$

$$1\ 1\ 1 = (1 \times 2^2) + (1 \times 2^1) + (1 \times 2^0) = 7$$

Digital Logic Circuits

- Since the 1960s manufacturers have developed integrated circuits (ICs), each designed to perform specific operations on digital signals.
- Logical operations such as AND, OR, NOT etc. are basic building blocks used to create more complex functions used by digital computers.
- A register, latch or flip-flop is a simple memory device that can store 1 bit of data.

Register and Latch Circuit Model

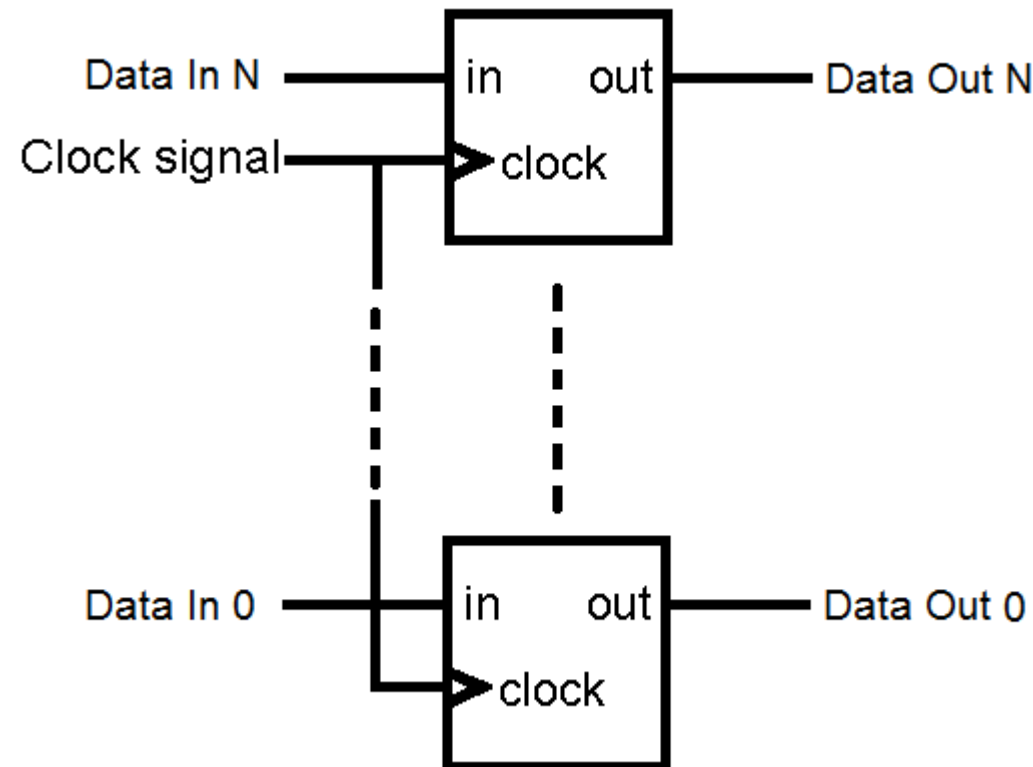

When Clock signal changes from '0' to '1' state of Data in is stored and transferred to Data Out.

Simple Digital Output Port

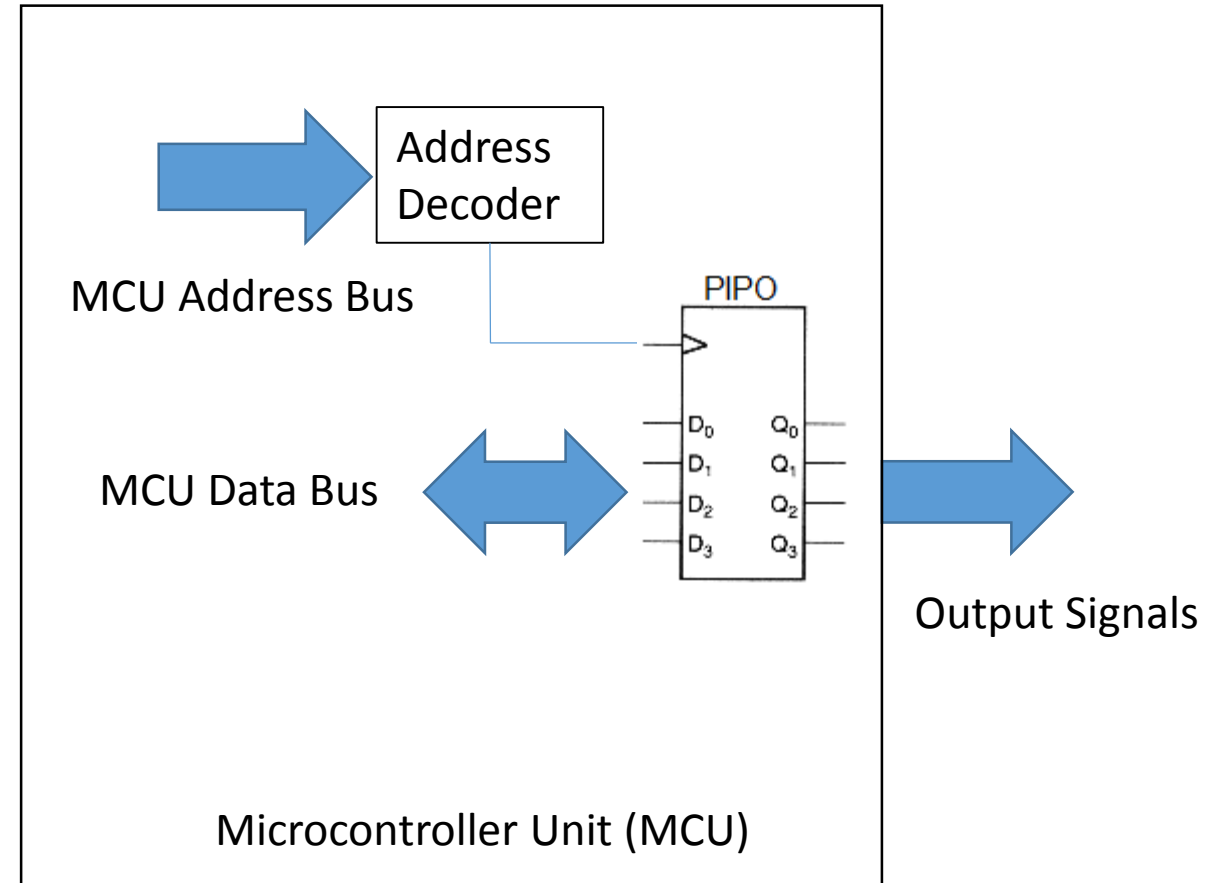

- A simple output port comprises a register.
- Registers are logic circuits that can store binary data (bits).
- A flip-flop circuit can store 1-bit of data.
- D-types represent one of a number of types of flip-flop circuit.
- To write to the flip-flop we present data on the 'D' input and then toggle the clock (the write occurs on the low-high transition)

Simple Output Port

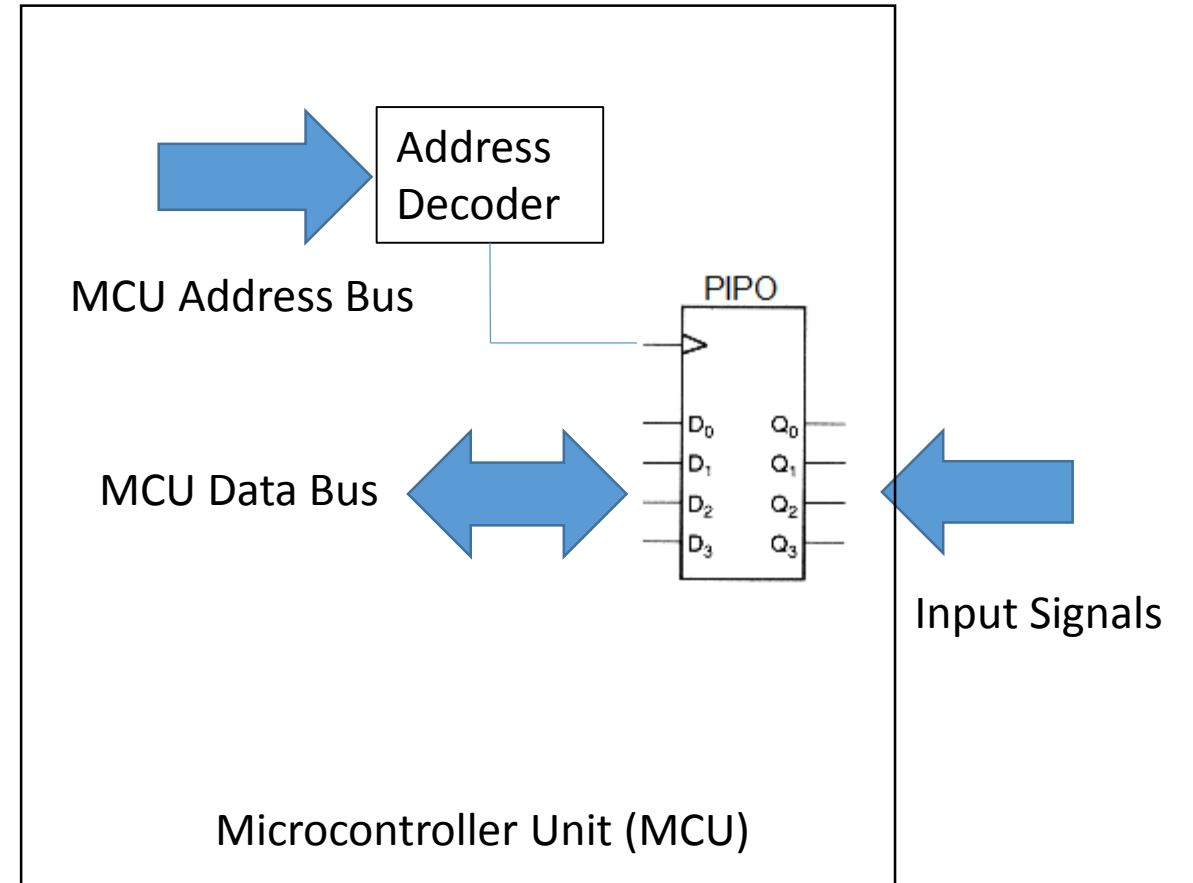

- To make a simple output port we just need to add an address decoder.
- The address decoder recognises a specific address.
- The decoder generates a clock when this address is issued by the MCU.
- The decoder itself is another very simple logic circuit.

Raspberry Pi SoC

- The Raspberry Pi is implemented as a custom System on Chip (SoC) designed / produced by Broadcom. <https://www.broadcom.com/>
- The design is documented at <https://www.raspberrypi.org/documentation/hardware/raspberrypi/>
- There are 4 Raspberry Pi variants:
 - Pi Zero
 - Pi One - BCM2835
 - Pi Two – BCM2836
 - Pi Three – BCM2837
- Only documentation of BCM2835 is generally available.

Connecting a LED to GPIO

- GPIO outputs can only supply (drive) a limited amount of current.
- The value of 'drive' for each pin is programmable.
 - <https://www.scribd.com/doc/101830961/GPIO-Pads-Control2>
- Never demand any output pin handles more than 16 mA.
- Minimum value of series Resistor

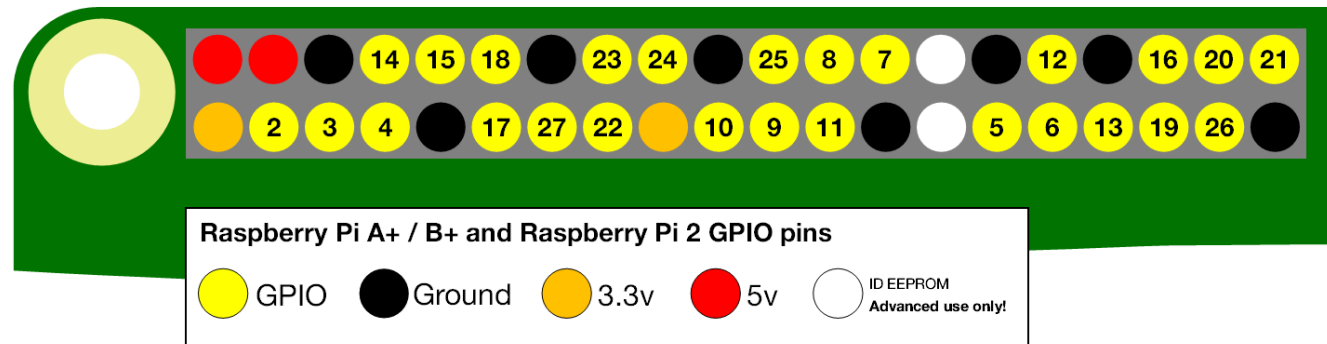

$$R_{min} = \frac{V}{I} = \frac{(3.3 - 0.7)V}{16 \text{ mA}} = 162 \text{ Ohms}$$

$$P = VI = (3.3 - 0.7) \times 0.016 = 41 \text{ mW}$$

Pin Numbering

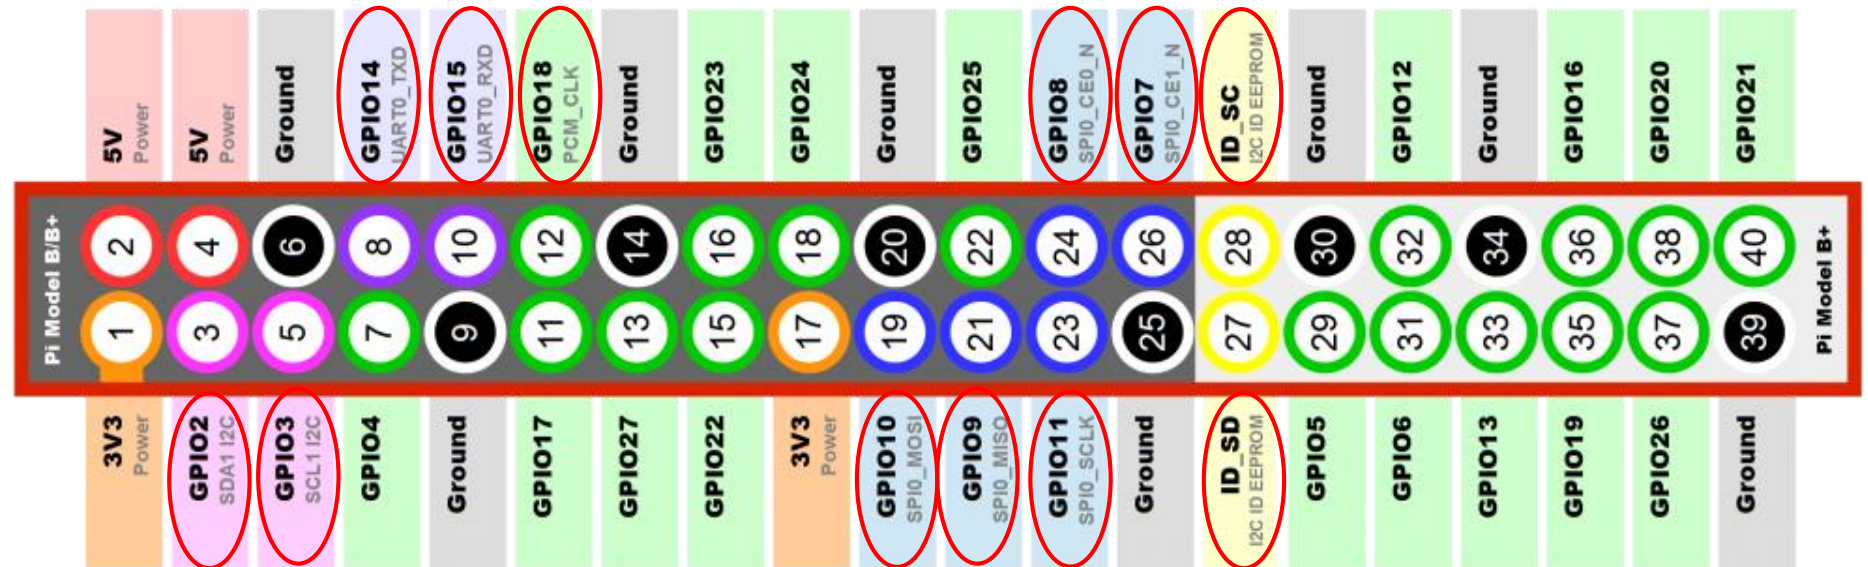

- Individual GPIO pins ('channels') are referenced using one of two conventions known as GPIO numbering and physical numbering.
 - GPIO numbering refers to the pin by its logical channel name (e.g. GPIO9)
 - Physical numbering refers to the channel by its pin ID (e.g. Pin 21)
- Before writing or reading a channel you must first select the pin numbering scheme being used.

Alternate Function

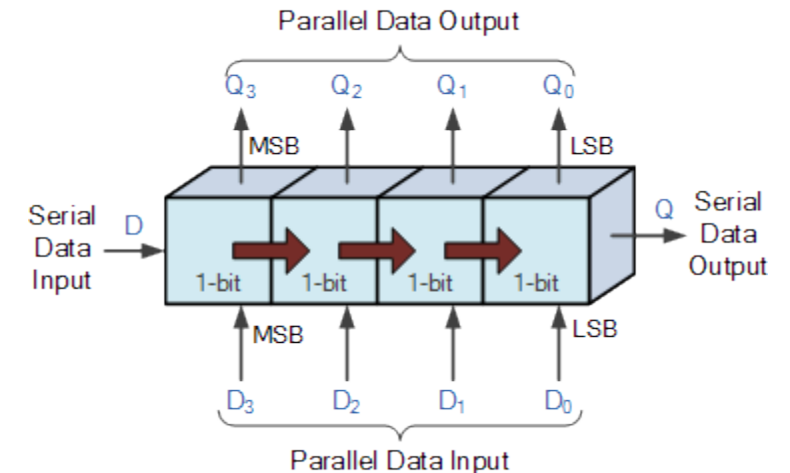

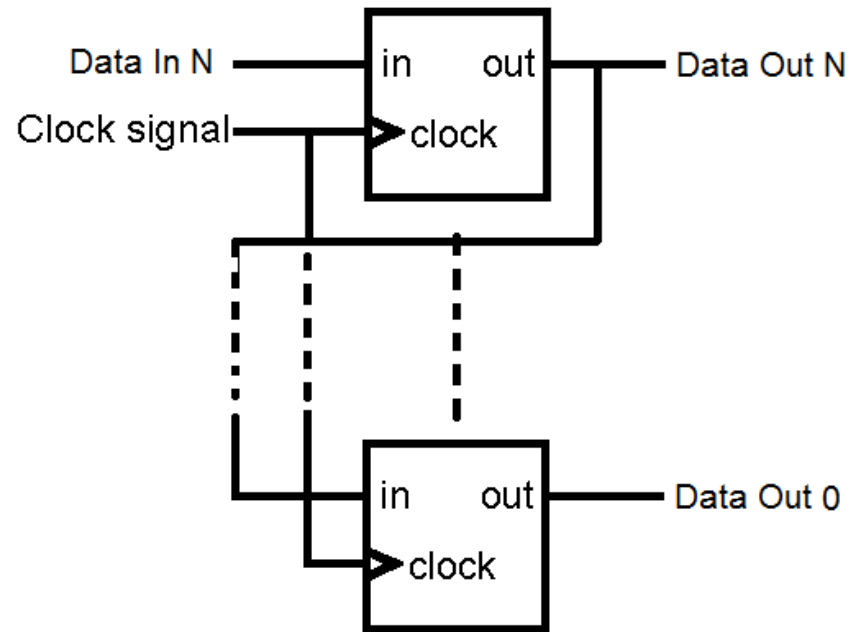

- To reduce the overall pin count (i.e. cost of fabricating the SoC) some GPIO pins are shared with other peripherals; many providing serial data interface.
 - UART
 - I2C
 - SPI
- The big advantage of serial data transmission is it only requires 2 (or 3) signals.

Inter-Integrated Circuit Bus (I²C, I2C)

- I²C (Inter-Integrated Circuit), pronounced I-squared-C, is a multi-master, half-duplex, multi-slave, single-ended, serial computer bus invented by Philips Semiconductor.
- The bus comprises clock (SCL) and serial data (SDA) lines

I²C Message Protocol

- I²C is a 2-wire interface designed to connect low speed peripherals.
- Bit rate is 100 kbit/s but since most transactions involve passing slave address actual data rate is about half this figure.
- Uses a 7-bit or 10-bit address space
- The master initially sends a start bit followed by the slave address, followed by a single bit representing whether it wishes to write(0) to or read(1) from the slave.
- If the slave exists on the bus then it will respond with an ACK bit (active low for acknowledged) for that address. The master then continues in either transmit or receive mode (according to the read/write bit it sent), and the slave continues in its complementary mode (receive or transmit, respectively).

I²C Message Protocol

- I²C defines basic types of messages, each of which begins with a START and ends with a STOP:
 - Single message where a master writes data to a slave;
 - Single message where a master reads data from a slave;
 - Combined messages, where a master issues at least two reads and/or writes to one or more slaves.
- In a combined message, each read or write begins with a START and the slave address. After the first START, these are also called repeated START bits; repeated START bits are not preceded by STOP bits, which is how slaves know the next transfer is part of the same message.

Serial Peripheral Bus (SPI)

- SPI is a full-duplex, synchronous, serial bus developed by Motorola.
- SPI devices communicate using a master-slave architecture with a single master. The master device originates the frame for reading and writing. Multiple slave devices are supported through selection with individual slave select (SS) lines.

Software Libraries

- Software libraries make using GPIO, SPI, I2C etc. much simpler.
- Need to select a library with functions that can easily be integrated within programs written in a target language.
- Bare GPIO and Serial Bus Standards are generally supported by the Open Source community.
- Manufacturers using bespoke protocols provide their own libraries – in many cases these are ported to Raspberry Pi by the user community.

Raspberry Pi GPIO Library

- A number of libraries exist for interfacing to GPIO
 - C / C++ - <http://www.airspayce.com/mikem/bcm2835/>
 - Java - <http://pi4j.com/>
 - Python - <https://sourceforge.net/projects/raspberry-gpio-python/>
<https://pythonhosted.org/RPIO/>
- Raspbian ships with RPi.GPIO Python library but you might wish to update to the latest version
<http://www.raspberrypi-spy.co.uk/2012/05/install-rpi-gpio-python-library/>
- `$ find /usr | grep -i gpio` will recursively search /usr directory for files containing the string “gpio”.
Look for lines containing 0.6.3.egg-info (0.6.3 is the version).
- Consult <https://sourceforge.net/p/raspberry-gpio-python/wiki/Examples/>

Summary

- The GPIO peripheral is complicated because manufacturers are trying to squeeze as much functionality as possible onto a few device pins (pins are expensive).
- Many devices use a serial data bus to save pins.
- To successfully use the GPIO we need to use a library.
